ANAMOLY DETECTION

Anamoly Detection is also known as outlier detection. Let us understand the Outlier in the Laymen language. For instance, you are asked to remove the rotten tomatoes from bucket because if not separated it will also spoil the other good tomatoes.

Similarly, there are variable/features/data points which are of no use or making no difference but could be responsible for greater loss. Thus we need to find the Outliers and remove them for better accuracy.

The noise are the data points which are detected as the outliers.

Anamoly Detection is categorized into three broad categories -

- 1. **Supervised Anamoly Detection** In Supervised Detection, there is a classifier which classifies whether the data pints is Normal or Abnormal.
- 2. **Unsupervised Anamoly Detection** It detects the anomalies in the given dataset by assuming that the testing dataset contains the least fit to the remainder of the data set.
- 3. **Semi-Supervised Anamoly Detection** The training data set to construct the normal behaviour to the model and it checks the test data for the likelihood by the experience the model generated.

Anamolies and is classifications

Anamoly is use to identify the rare items, suspcious items, events and outcomes which can raise a harm to the model.

The anamolies have several classifications -

1. **Point anamolies** When a single data point is too far from the rest data points which makes it merely impossible to make the cluster or map it to the data points or cluster then we simply remove such data points. This is called the point anamolies.

2. **Contextual anamolies** If the abnormality is context specific, For instance investing 1000 rupee everyday on buying shoe since you play football is normal, but odd anyway.

3. **Collective anamolies** A set of data instance is responsible to track this anamoly. If someone is remotely using a machine and extracting the information to the local host. It gives the sign of the cyber attack.

Anamoly Detection is similar to Novelty detection but not completly similar. Novelty Detection is mainly concerned of identifying the unobseverd pattern in the observations.

Anamoly Detection Techniques

Simple Statistical Methods - The simple methods to find the irregularities in data points that deviate from common statistical properties of distribution including mean, median, standard deviation, etc.

Anamoly detection techniques

Isolation Forest Anomaly Detection Algorithm

Density-Based Anomaly Detection (Local Outlier Factor) Algorithm

Support Vector Machine Anomaly Detection Algorithm

Applications of Anamoly detection

- 1. Intrusion Detection
- 2. Fraud Detection
- 3. Fault Detection
- 4. System Health Monitoring
- 5. Event Detection in networks
- 6. Detecting Natural disturbances.

Maths used in Anamoly Detection

Problem Statement

Credit Card Fraud Detection

Data Preprocessing and EDA

Why Data processing and visualization is important?

It is very important to clean the data(preprocess) before using it to fit the model. The method helps in removing the outliers and make the data standardized.

To understand the data more easily and widely we visualize the data

Now, let us preprocess the data, visualize the data and fit the data into the model.

```
In [ ]:
```

```
1 # importing the libraries
2
3 import pandas as pd
4 import numpy as np
```

[Recaller -]

- 1. Pandas It is an open-source library which we can use to manipulate, create or wrangle the data.
- 2. Numpy NumPy stands for 'Numerical Python'. It is a python package used to perform scientific computations like performing linear algebra, arranging the data, dropping the data, etc.

```
#Importing the dataset so that we can use it for the further proceedings
db = pd.read_csv('creditcard.csv', sep=',')
```

Now let us define the basic information to the dataset

In []:

```
1 # Describing the data which includes the data count, mean, min, max, standard of
2 db.describe()
```

Why to handle the missing values?

• If the missing value is not handled, the programmer would end up with the interpretation of the inaccurate results and thus the model would not fit.

There are several ways of handling the missing values in the data:

- 1. Remove rows with missing values
- 2. Set some value for missing values.
- 3. You can set the median or mean for missing values.

There are several methods to check the missing values

```
# Checking out the missing values for the dataset so that we can remove it and
total = db.isnull().sum().sort_values(ascending=False)

percent = (db.isnull().sum()/db.isnull().count()).sort_values(ascending=False)
missing_data = pd.concat([total, percent], axis=1, keys=['Total', 'Percent'])
missing_data
```

Out[9]:

Total

Percent

IUlai	Percent
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036
1	0.000036

0	0.000000
	1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1

After clearly analyzing the missing value we can remove the last column from the dataset as only one column is given that is time and everything is empty

```
In [ ]:

1  df = db.drop(db.index[[27818]])
```

Now again checking the missing value

```
total = df.isnull().sum().sort_values(ascending=False)
percent = (df.isnull().sum()/df.isnull().count()).sort_values(ascending=False)
missing_data = pd.concat([total, percent], axis=1, keys=['Total', 'Percent'])
missing_data
```

What is Correlation?

Correlation is used to check how strongly the variable is depended on the another variable. There are three typer of correlation.

- 1. Negative Correlation When the varibles change in different directions
- 2. Positive Correlation when the variables chane in the same direction.
- 3. Neutral Correlation when there is no relationship between the variables.

There are several methods to check the correlation. Pearson's Correlation, Spearman's Correlation, etc.

Hence showing the correlation of the data with other data points

In []:

```
1 #Understand the distribution of the data
2 df.tail()
3
```

Model Fitting

Why it is important to fit the model?

If your model is not fitting the data accurately, the outcome it will produce would be inefficient for taking the decision in the practical use.

There are three ways the model can get fit. It is shown by the simple figure.

Let us take a definition to underfitting, overfitting and appropriate fitting.

Overfitting - The performance on the data is good but the accuracy generates overfits(poor) the data.

Underfitting - The performance is poor and the accuracy generated by the model is also poor

Appropriate fitting - The performance and the generalization are both good

```

We can also improve on this accuracy by increasing the sample size or use deep learning algorithms however at the cost of computational expense. We can also use complex anomaly detection models to get better accuracy in determining more fraudulent cases

Thus we can use autoencoder.

Advantages of Anamoly Detection

- 1. It can Monitor the data source, networks, users, etc.
- 2. It can identify the Security threads.
- 3. It can find the trend of the unusual behavior of the data set and handles the security and safity.
- 4. It can identify key outliers.

Disadvantages

The biggest Disadvantage is that it cannot identify the novelty attacks and the various existing attacks.
